

Generic Name: Dapagliflozin

Trade Name: Farxiga® (far-SEE-guh)

Strengths: 5 mg, 10mg (oral tablet)

Source of Supply: Bristol-Myers Squibb, Princeton NJ (Manufacturer)
AstraZeneca (Marketing)
No generic available at this time

FDA Approval Date: January 8, 2014

Pharmacologic Category: Anti-diabetic Agent
Sodium-Glucose Co-Transporter 2 Inhibitor (SGLT-2 Inhib.)

Mechanism of Action: Dapagliflozin increases the amount of glucose that gets excreted in the urine through inhibition of the SGLT2 in the proximal tubules of the kidney. Inhibition of the SGLT-2 transporter reduces the amount of filtered glucose that gets reabsorbed through the tubular lumen. The SGLT-2 is the main mechanism by which filtered glucose gets reabsorbed in the kidney. Through this mechanism, dapagliflozin reduces plasma glucose concentrations.

FDA Approved Indications: Improvement of glycemic control in Type 2 Diabetes Mellitus, as an adjunct to diet and exercise

Non-FDA Indications: None

Pharmacy Recommendation: Adding dapagliflozin to the [Hospital X] formulary is recommended at this time. No SGLT-2 Inhibitors currently exist on [Hospital X] formulary and this class of drugs has a unique mechanism of action that is not represented by the other non-insulin anti-diabetic drugs available on formulary. This drug is relatively well tolerated. Canagliflozin would be an alternative option for formulary addition, but has higher protein binding than dapagliflozin, which increases the likelihood for drug-drug interactions (e.g., warfarin). Canagliflozin also carries a risk of hyperkalemia (>10% frequency) whereas dapagliflozin does not. Empagliflozin (the third and final drug in this class) was FDA approved in August 2014 and is not yet commercially available. Although dapagliflozin use is associated with mycotic genital infections, this appears to be a class effect and simply requires monitoring. For patients coming in to the hospital on an SGLT-2 Inhibitor, it would be advantageous to allow them to continue taking a drug in this class for continuity of care. However, it should be noted that SGLT-2 inhibitors like dapagliflozin can cause hypovolemic dehydration, a condition that has the potential to exacerbate many conditions found in the acute care hospital setting.

Current Formulary Alternatives: No SGLT-2 Inhibitors currently exist on [Hospital X] formulary. See the table below for the non-insulin anti-diabetic agents that are available on [Hospital X] formulary. According to American Association of Clinical Endocrinologists 2013 guidelines for diabetes management, metformin is the first line agent for treatment of T2DM. If there is an intolerance or contraindication to metformin, AACE suggests those agents indicated as such in the table. Beyond that, agents can be added on to metformin (or an acceptable alternative) to achieve blood glucose control. Although the AACE has an algorithm for how adjunctive agents should be added on, they also recognize that treatment decisions should be highly individualized based upon the pros and cons of each agent. As stated in the guideline, the algorithm “cannot capture many decisions that a physician must make to treat individual patients” (p.14).⁴ Thus, a list of all of the non-insulin therapies available at [Hospital X] are provided here.

| <i>Non-Insulin Anti-diabetic Agent Available on [Hospital X] Formulary</i> | <i>Route</i> | <i>Suggested hierarchy of usage when dual or triple therapy is needed (AACE)⁴</i> | <i>Acceptable Therapeutic Alternative to Metformin when intolerance or contraindication to metformin (AACE)⁴</i> | <i>Therapeutic Class</i> |
|--|--------------|--|---|--|
| metformin (Glucophage) | PO | 1-first line / backbone | --- | Biguanide |
| liraglutide (Victoza) | SQ | 2 | Yes | GLP-1 Receptor Agonist |
| linagliptin (Tradjenta) | PO | 3 | Yes | DPP-4 Inhibitor |
| pioglitazone (Actos) | PO | 4 | Use with caution due to propensity for causing weight gain | Thiazolidinedione (TZD) |
| dapagliflozin (Farxiga), canagliflozin (Invokana) *not currently on [Hospital X] formulary* | PO | 5 | Yes | SGLT2 Inhibitor |
| acarbose (Precose) | PO | 6 | Yes | Alpha-Glucosidase Inhibitors |
| repaglinide (Prandin) | PO | 7 | Use with caution due to propensity for causing weight gain and hypoglycemia | Meglitinide Derivatives (glinides) |
| tolazamide (generic only) | PO | 7 | Use with caution due to propensity for causing weight gain and hypoglycemia | Sulfonylurea, 1 st Generation |
| glimepiride (generic only) | PO | 7 | Use with caution due to propensity for causing weight gain and hypoglycemia | Sulfonylurea, 2 nd Generation |
| glipizide (Glucotrol XL) | PO | | | |
| glyburide (Diabeta, Micronase) | PO | | | |

Advantages of medication over current formulary options:

Would allow continuity of care for patients coming into the hospital already on an SGLT-2 Inhibitor; lower risk of GI side effects than some of the other agents; can provide additional hemoglobin A1c lowering when metformin or other agents have allowed the patient to reach goal; may help with weight loss; has been suggested in AACE guidelines as an acceptable alternative to metformin when there is a contraindication or intolerance to metformin; unique mechanism of action is non insulin-dependent;

Disadvantages of medication over current formulary options:

New agent (still relatively unknown what adverse events are most likely, especially cardiovascular effects); contraindicated in renal failure; rather high protein binding (could compete with other highly protein bound drugs such as warfarin); increase in genital fungal infections and urinary tract infections due to dapagliflozin-induced glucosuria; hypovolemic dehydration is a risk due to its mechanism of action (this could be a problem in diabetic patients, most of whom are already on blood pressure lowering therapies in concordance with established guideline recommendations); relatively high risk of hypoglycemia when combined with other anti-diabetic agents (40%); correlation with bladder cancer remains unknown

Dosage Forms:

Oral Tablet (5mg, 10mg)

Storage / Stability:

Store at 20-25°C (68-77°F)

Dosage Regimen:

- Initial: 5 mg one daily in the morning (can be taken without regard to meals)
- Maximum: 10 mg once daily

Use in Special Populations:

| <i>Agent</i> | <i>Geriatric</i> | <i>Pediatric</i> | <i>Renal Impairment (eGFR in units of mL/min/1.73m²)</i> | <i>Hepatic Impairment</i> |
|---------------|-----------------------------|--|---|--|
| Dapagliflozin | utilize normal adult dosing | has not been studied in patients under 18 years of age | eGFR <60: Not recommended eGFR <30: Contraindicated Hemodialysis: Contraindicated | Mild-Moderate (Child-Pugh Class A/B): No adjustment necessary |
| Canagliflozin | | | eGFR 45 to <60: Max dose 100mg daily eGFR 30-45: Not recommended eGFR <30: Contraindicated Hemodialysis: Contraindicated | Severe (Child-Pugh Class C): Has not been studied |

Pregnancy Category: C (Adverse events observed in animal studies)

Use During Breast-Feeding: Unknown if dapagliflozin is excreted in breast milk. Due to potential risk of causing harm to nursing infant, it is recommended to either discontinue the drug or discontinue breast-feeding.

Pharmacodynamic / Kinetic Comparisons:

| <i>Agent</i> | <i>Protein Binding</i> | <i>Metabolism</i> | <i>Bioavailability</i> | <i>Half-life Elimination</i> | <i>Excretion</i> |
|--------------------------|--------------------------------|--|------------------------|---|---|
| dapagliflozin (Farxiga) | 91% | Glucuronidation to inactive metabolite (major pathway) CYP-mediated metabolism (minor pathway) | 78% (PO) | 13 hrs | Urine (75%) Feces (21%) |
| canagliflozin (Invokana) | 99% | Glucuronidation to inactive metabolites (major pathway) CYP-mediated metabolism (minor pathway) | 65% | 10.6-13 hrs | Urine (33%) Feces (42% unchanged) |
| metformin (Glucophage) | Negligible | Not hepatically metabolized | Fasting: 50-60% (PO) | 4-9 hrs | Urine (90% unchanged; active secretion) |
| liraglutide (Victoza) | >98% | Metabolized to DPP-IV enzyme | 55% (SQ) | 13 hrs | Urine (6%) Feces (5%) |
| linagliptin (Tradjenta) | 70-80% | Not extensively metabolized | 30% | 12 hrs (terminal saturable binding >100hrs) | Urine (5% unchanged) Feces (80% unchanged) |
| pioglitazone (Actos) | >99% Active metabolites (>98%) | CYP2C8, 3A4 (99%) Active and inactive metabolites | --- | 3-7 hrs (parent) 16-24 hrs (total) | Urine (15-30%) Feces As metabolites |

Major Adverse Reactions:

- Hypoglycemia (40% when combined with insulin or other oral anti-diabetic therapy)
- Mycotic genital infections (Females, 8%; Males, 3%)
- Nasopharyngitis (7%)
- UTI (5%)
- Polyuria (4%)
- Dyslipidemia (3%)
- Nausea (3%)
- Back pain (3%)
- Hypovolemia (dehydration, intravascular volume depletion) (1%)
- Bladder neoplasms (<1%)
- Bone fracture in patients with moderate renal impairment (frequency not defined)
- Decreased renal function (frequency not defined)

Contraindications:

- Severe renal impairment, ESRD, patients on dialysis
- Patients in Diabetic Ketoacidosis (DKA)
- Active bladder cancer

Warnings / Precautions:

- Those with a history of genital mycotic infections or uncircumcised males are at greater risk of developing such an infection while taking dapagliflozin.
- Hypersensitivity reactions (angioedema, urticaria) can occur in some patients; discontinue treatment if this occurs.
- Correct intravascular volume depletion prior to initiation and monitor for hypotension / dehydration while taking dapagliflozin. Elderly age, concomitant use of anti-hypertensive medications, and those with low systolic blood pressure are at increased risk.
- May cause elevations in LDL cholesterol; monitor and treat as needed.
- Elderly and patients with pre-existing renal impairment may be at increased risk of renal abnormalities while taking dapagliflozin. Monitor renal function at baseline and periodically throughout treatment; discontinue if eGFR<60 mL/min/1.73m².
- Although causal relationship has not been definitively established, newly diagnosed bladder cancer occurred more frequently in dapagliflozin patients. Do not use this agent in patients with active bladder CA and use caution in patients with h/o bladder CA (weigh risks / benefits).
- Dapagliflozin has not been studied in patients with Type I Diabetes Mellitus; do not use this agent.
- On ISMP's high alert medication list (as are all oral anti-diabetic medications that have the potential lower blood sugar)

Monitoring Parameters:

- Blood glucose
- Hemoglobin A1c
- Renal function (at baseline, and then periodically during therapy)
- LDL
- Genital mycotic infections
- Blood pressure
- Hydration status

Drug Interactions:

- Substrate of P-glycoprotein, UGT-1A9
- Dapagliflozin may increase effect / levels of:
 - Duloxetine
 - Other Hypoglycemia Agents
 - Hypotensive Agents
- Dapagliflozin's effect / levels can be increased by:
 - Androgens
 - Barbiturates
 - Herbs w/ hypoglycemic properties
 - MAOI's
 - Pegvisomant
 - Salicylates

- SSRI's
- Dapagliflozin's effect / levels can be decreased by:
 - Corticosteroids (inhaled or systemic)
 - Danazol
 - Loop Diuretics
 - LHRH Analogs
 - Somatropin
 - Thiazide Diuretics

Therapeutic Comparisons:

| <i>Agent</i> | <i>Expected % Decrease in A1c lowering with Monotherapy⁵</i> | <i>Advantages⁴</i> | <i>Disadvantages⁴</i> | <i>Main Adverse Effects⁵</i> |
|--|---|--|--|--|
| Biguanide | | | | |
| metformin (Glucophage) | 1-2 | Low risk of hypoglycemia Potential for modest weight loss Robust A1c lowering Good cardiovascular safety record | GI SE (dose-related) can preclude use in 10-15% of pts Renally eliminated → CI in renally impaired due to increased risk of Lactic Acidosis Vitamin B12 deficiency | Lactic Acidosis (Boxed Warning) GI distress (n/d) Weakness |
| Glucagon-like Peptide-1 Receptor Agonists (GLP-1) | | | | |
| liraglutide (Victoza) | 1 | Robust A1c lowering Potential for 1-4kg weight loss Low hypoglycemia risk Reduce both fasting and post-prandial glucose values No adverse CVD outcomes reported as of yet Administered once daily | Injectable (requires more instruction) Hypoglycemia risk increases when combined with SU C-cell hyperplasia and pancreatitis found in rodents, but confirmatory studies still lacking Should not be used in combination with DPP-4 inhibitors | GI (n/v/d) |
